4S - Space Systems for Safety and Security

Space Systems for Safety & Security (4S) represents a consolidation of and increase in ESA's efforts to support, under a new ARTES thematic framework:

- European satellite operators and manufacturing industry, to ensure that new levels of security, robustness and resilience become mandatory requirements of space-based communication solutions globally.
- European downstream industry and service providers, in delivering relevant space-based solutions and business models for innovative, economically sustainable downstream services addressing global security needs.

Integration of satellite and terrestrial railway control networks B00 B	Activity Ref.	Activity Title	Estimated Price to ESA (kEuro)	Category
necessary also for the integration of satellite and terrestrial railway control networks. Testing will be carried out through realistic packet level simulations via a developed software-defined radio testbed. Enabling the use of satellite for railway control communication The European Union Agency for Railways (ERA) and the International Union of Railways (UIC) have started to define the Future Railway Mobile Communication System (FRMCS) as a successor of the current GSM-R system. FRMCS is planned to be operational before GSM R's predicted saturation in 2030, and SATCOM is identified as a promising component of the future system. The integration of satellite into FRMCS will require developing signalling mechanisms that enable both networks to exchange configuration, management and monitoring information. Hence, this activity will develop the control and management protocol stacks enabling railway control communication via satellite in compliance with FRMCS. Signalling procedures will be defined and tested, including handshaking, registration, call establishments, prioring access, handovers, outage detections and reporting. The protocols will be 5G compatible to ensure full integration into the FRMCS railway control services. Multilink capabilities and integration with the user plane will be studied. Packet-level simulation will be carried out to test and evaluate the protocol stacks. A prototype of the control and management protocols will be implemented in a Software Defined Radio (SDR) testbed. End-to end testing will be carried out including integration with the user plane. Summary report, control and management protocol stacks as well as a software defined radio testbed.
